Returns should be measured by the Return rate %, Total number of returns, and Cost of returns. Return rate % should be used when a product is having similar sales, but one is having a much higher return rate which signals potential problems with product. Using the Total number of Returns is best when high volume of returns could potentially overwhelm support and indicate systematic issues. Lastly, using total Cost of returns is useful for a high-cost product is returned even in small numbers which may have greater financial impact than many small-item returns.

- Potential Issues: -Product quality issues, -Operational or Supplier Errors, -Shipping and Handling Damage, -Mismatch Between Product, Description, and Reality, -Customer Behavior

The return analysis reveals clear patterns in product performance, trends, regional behavior, and customer activity. Certain sub-categories like Binders and phones happen to show a disproportionately high return rate. Additionally, returns happen to peak in May and October, suggesting a link to seasonal or promotional factors.

To address these issues, the business should prioritize high-return products for quality reviews, tailor marketing and strategies for peak months, and focus on customer and regional feedback to uncover the root causes. Using return rate as the key metric rather than just the return volume provides a balanced view of the performance of product. With these insights, the business can target and implement these improvements, optimize their return policies, and enhance overall customer satisfaction while reducing unnecessary costs.
